### Growth Retardant Rates for Bedding Plant Production in Northern Climates

John Erwin, Department of Horticultural Sciences, University of Minnesota

**Introduction:**
Growth retardant application can be complicated. There are new growth regulators, new species and cultivars, and new ways of applying regulators that can greatly affect the rates, frequency and kind of growth retardant that is used. To make things more complicated, most growth retardant recommendations are written for regions that have significantly warmer day and night temperatures, i.e. the south. As a result, recommended rates are often too high for commercial production in the northern United States. In addition, the rates of application in the northern United States during the spring change substantially as weather conditions change dramatically from March to May.

The table below summarizes growth retardants that are effective for control of stem elongation for each species listed during March, April and May. Rates are based on effective rates in the north. Presented rates are based on results of various reports (from a variety of sources), reduced rates from reports for crops produced in the south, and personal experience. Additional growth retardants may be effective, but may not have been tested to date or I may not have observed whether they are effective of not.

Application technique has a huge impact on the effectiveness of a growth retardant application on a crop. This is especially the case with Bonzi and Sumagic where effectiveness can vary substantially based on how a plant is sprayed and whether and retardant drips onto the media. Because the effectiveness of each of these growth retardants varies with application technique and the greenhouse in which the plants are grown, recommended rates should be viewed as a starting point. Also, it is also best to start at a lower rate and increase the application

<table>

<tr>
<th>Growth Retardant</th>
<th>Description</th>
<th>Rate Range</th>
<th>Application Technique</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>A-Rest</strong></td>
<td>An older growth retardant that has been used primarily to control stem elongation in Easter lilies. Although it is effective on a number of species, its use has been limited because of the cost of A-Rest. However, often A-Rest a viable option when B-9 or Cycocel are not effective and when a grower does not want the degree of stem elongation inhibition that can occur after a Bonzi or Sumagic application. In addition, A-Rest use in the plug industry is increasing in combination with other growth retardants, i.e. in a tank mix. Key characteristics of A-Rest include broad efficacy, spray volume is not as critical as other retardants (not active in the media), typical concentrations are from 25-100 ppm, little or no phytotoxicity, takes 3-5 hours for complete absorption, ‘greens’ foliage.</td>
<td>8 ppm when applied as a spray, effectiveness is doubled when the chemical is applied to the media, foliar phytotoxicity is exhibited on vinca, it is absorbed in 5 – 10 minutes.</td>
<td>Coated, Drip, Spray</td>
</tr>
<tr>
<td><strong>Bonzi</strong></td>
<td>Bonzi is a new growth retardant that is one of a new class of materials that have broad efficacy at much reduced concentrations compared to B-9 and Cycocel. Key characteristics of Bonzi include broad efficacy, material is effective when absorbed through the stem or root (not leaves!), spray volume is very important, typical rates are from 5 – 20 ppm when applied as a spray, effectiveness is doubled when the chemical is applied to the media, foliar phytotoxicity is exhibited on vinca, it is absorbed in 5 – 10 minutes.</td>
<td>5 – 20 ppm when applied as a spray, effectiveness is doubled when the chemical is applied to the media, foliar phytotoxicity is exhibited on vinca, it is absorbed in 5 – 10 minutes.</td>
<td>Coated, Drip, Spray</td>
</tr>
<tr>
<td><strong>B-9</strong></td>
<td>B-9 is perhaps the most widely used growth retardant. Key characteristics of B-9 include broad efficacy, spray volume is not as critical as other retardants (not active in the media), typical concentrations are from 1,000 – 5,000 ppm, little or no phytotoxicity, takes 3-5 hours for complete absorption, ‘greens’ foliage.</td>
<td>Concentrations are from 500 – 1,500 ppm, little or no phytotoxicity, takes 3-5 hours for complete absorption, ‘greens’ foliage.</td>
<td>Coated, Drip, Spray</td>
</tr>
<tr>
<td><strong>Cycocel</strong></td>
<td>Cycocel is widely used to control stem elongation of geraniums, hibiscus and begonias. Key characteristics of Cycocel include broad efficacy, spray volume is not as critical as other retardants (not active in the media), typical concentrations are from 500 – 1,500 ppm, foliar phytotoxicity (yellowing) can occur when &gt;1,000 ppm is applied, takes 3-5 hours for complete absorption, ‘greens’ foliage.</td>
<td>5 – 20 ppm when applied as a spray, effectiveness is doubled when the chemical is applied to the media, foliar phytotoxicity is exhibited on vinca, it is absorbed in 5 – 10 minutes.</td>
<td>Coated, Drip, Spray</td>
</tr>
<tr>
<td><strong>Sumagic</strong></td>
<td>Sumagic is also newer growth retardant that is one of a new class of materials that have broad efficacy at much reduced concentrations compared to B-9 and Cycocel. Key characteristics of Sumagic include broad efficacy, material is effective when absorbed through the stem or root (not leaves!), spray volume is very important, typical rates are from 1/4 – 8 ppm when applied as a spray, effectiveness is doubled when the chemical is applied to the media, it is absorbed in 5 – 10 minutes.</td>
<td>Concentrations are from 25-100 ppm, little or no phytotoxicity, takes 3-5 hours for complete absorption, ‘greens’ foliage.</td>
<td>Coated, Drip, Spray</td>
</tr>
</tbody>
</table>

**Application Techniques:**
The way a retardant is applied can greatly affect how much inhibition of elongation you get. In particular, mixing some growth retardants together or applying them to the media can greatly increase their efficacy.

**Tank Mixes:**
When the resulting inhibition of stem elongation from applying two
growth retardants together is greater than the inhibition in elongation that would have resulted from applying each retardant separately we say there is a ‘synergistic’ effect. When we mix two growth retardants together to increase the effectiveness of each we call it a ‘tank mix’. Tank mixes can help reduce growth retardant costs and can increase the effectiveness of growth retardants dramatically. The most common tank mix in northern climates is a combination of B-9 + Cycocel. Note that some tank mixes are listed below.

**Drenching:**

Drenching with Bonzi or Sumagic dramatically increases their inhibition of stem elongation. Growers can get into trouble when they allow these growth retardants to drip on media when doing a spray application. Therefore, it is very important that the most experienced sprayer apply these growth retardants and that a sprayer that delivers very uniform coverage be used. Very few drenches are listed below. However, postharvest drenches will be discussed in the future as a means to improve garden performance of some container and basket crops.

Rates listed below are only suggestions. The mention of these materials and rates in no way represents an endorsement of these products by the University of Minnesota.

**NOTE** - the table below lists all the options available to a grower for height control. You choose which one you prefer! The presence of a ‘+’ notes that that retardant should be added to the retardant immediately below it in that column. For instance, for Ageratum in May, 750 ppm B-9 can be added to 500 ppm Cycocel (retardant immediately below it) to make a tank mix.

</tbody>
</table>

**Notes:**
- ppm: Parts per million
- B-9, Sumagic, Bonzi, Cycocel, A-Rest are specific plant growth regulators.
- The numbers represent the concentration of the growth regulator applied.
